Our Refinements

Closing Thoughts

Background

Andrews, Lewis, and Lovejoy denoted the number of partitions with designated summands of weight n by the function $PD(n)$.

Using this notation and the example above, we know $PD(4) = 10$.

In the same paper, Andrews, Lewis, and Lovejoy also considered the restricted partitions with designated summands wherein all parts must be odd, and they denoted the corresponding enumeration function by $PDO(n)$.

Background

Thus, from the example above, we see that $PDO(4) = 5$, where we have counted the following five objects:

Function

Our Refinements

Closing Thoughts

Background

Instead of focusing on congruence properties satisfied by $\text{PDO}(n)$, I want to turn our attention to the following curious identity:

Theorem: For all $n \geq 0$,

$$\text{PDO}(2n) = \sum_{k=0}^n \text{PDO}(k)\text{PDO}(n - k).$$

Background

Instead of focusing on congruence properties satisfied by $\text{PDO}(n)$, I want to turn our attention to the following curious identity:

Theorem: For all $n \geq 0$,

$$\text{PDO}(2n) = \sum_{k=0}^n \text{PDO}(k)\text{PDO}(n-k).$$

From a generating function perspective, this is equivalent to proving that

$$\sum_{n \geq 0} \text{PDO}(2n)q^n = \left(\sum_{n \geq 0} \text{PDO}(n)q^n \right)^2.$$

Background

This identity implicitly appears in the original paper of Andrews, Lewis, and Lovejoy, as well as the 2024 *Integers* paper of Sellers.

Background

A Different View
of the Generating
Function

Our Refinements

Closing Thoughts

Background

Andrews, Lewis, and Lovejoy proved the following generating function result for $\text{PDO}(n)$.

Theorem: The generating function for $\text{PDO}(n)$ is given by

$$\sum_{n=0}^{\infty} \text{PDO}(n)q^n = \frac{f_4 f_6^2}{f_1 f_3 f_{12}}$$

where $f_r = (1 - q^r)(1 - q^{2r})(1 - q^{3r})(1 - q^{4r}) \dots$ is the usual q -Pochhammer symbol.

Background

This eta quotient representation of the generating function has been extremely helpful in proving congruences satisfied by $PDO(n)$.

A Different View of the Generating Function

In his 1921 *Proc. London Math. Soc.* paper, P. A. MacMahon generalized the notion of the generation function for the sum-of-divisors function by defining the following two generating functions:

$$A_k(q) = \sum_{0 < m_1 < m_2 < \dots < m_k} \frac{q^{m_1+m_2+\dots+m_k}}{(1-q^{m_1})^2 \dots (1-q^{m_k})^2},$$

A Different View of the Generating Function

In his 1921 *Proc. London Math. Soc.* paper, P. A. MacMahon generalized the notion of the generation function for the sum-of-divisors function by defining the following two generating functions:

$$A_k(q) = \sum_{0 < m_1 < m_2 < \dots < m_k} \frac{q^{m_1 + m_2 + \dots + m_k}}{(1 - q^{m_1})^2 \dots (1 - q^{m_k})^2},$$

$$C_k(q) = \sum_{0 < m_1 < m_2 < \dots < m_k} \frac{q^{2m_1 + 2m_2 + \dots + 2m_k - k}}{(1 - q^{2m_1 - 1})^2 \dots (1 - q^{2m_k - 1})^2}.$$

A Different View of the Generating Function

In his 1921 *Proc. London Math. Soc.* paper, P. A. MacMahon generalized the notion of the generation function for the sum-of-divisors function by defining the following two generating functions:

$$A_k(q) = \sum_{0 < m_1 < m_2 < \dots < m_k} \frac{q^{m_1 + m_2 + \dots + m_k}}{(1 - q^{m_1})^2 \dots (1 - q^{m_k})^2},$$

$$C_k(q) = \sum_{0 < m_1 < m_2 < \dots < m_k} \frac{q^{2m_1 + 2m_2 + \dots + 2m_k - k}}{(1 - q^{2m_1 - 1})^2 \dots (1 - q^{2m_k - 1})^2}.$$

These provide generalizations in the following sense.

A Different View of the Generating Function

Fix a positive integer k . Define $a_{n,k} := \sum s_1 \cdots s_k$ where the sum is taken over all partitions of n of the form

$$n = s_1 m_1 + \cdots + s_k m_k$$

with $0 < m_1 < \cdots < m_k$.

A Different View of the Generating Function

Fix a positive integer k . Define $a_{n,k} := \sum s_1 \cdots s_k$ where the sum is taken over all partitions of n of the form

$$n = s_1 m_1 + \cdots + s_k m_k$$

with $0 < m_1 < \cdots < m_k$.

When $k = 1$ this is simply $\sigma_1(n)$, the usual sum-of-divisors function.

A Different View of the Generating Function

Fix a positive integer k . Define $a_{n,k} := \sum s_1 \cdots s_k$ where the sum is taken over all partitions of n of the form

$$n = s_1 m_1 + \cdots + s_k m_k$$

with $0 < m_1 < \cdots < m_k$.

When $k = 1$ this is simply $\sigma_1(n)$, the usual sum-of-divisors function.

One can then show that

$$A_k(q) = \sum_{n=1}^{\infty} a_{n,k} q^n.$$

A Different View of the Generating Function

Next, consider $c_{n,k} := \sum s_1 \cdots s_k$ where the sum is taken over all partitions of n of the form

$$n = s_1(2m_1 - 1) + \cdots + s_k(2m_k - 1)$$

with $0 < m_1 < \cdots < m_k$.

A Different View of the Generating Function

Next, consider $c_{n,k} := \sum s_1 \cdots s_k$ where the sum is taken over all partitions of n of the form

$$n = s_1(2m_1 - 1) + \cdots + s_k(2m_k - 1)$$

with $0 < m_1 < \cdots < m_k$.

Note that for $k = 1$, this is simply the sum over all divisors j of n such that n/j is an odd number.

A Different View of the Generating Function

Note also that $c_{n,k} := \sum s_1 \cdots s_k$ is the sum of the products of the frequencies of all the parts in the odd-part partitions of n into exactly k parts.

A Different View of the Generating Function

OK, back to $\text{PDO}(n)$!

We now highlight two very important connections.

First, note that for a given k , $C_k(q)$ provides a natural refinement of the generating function of $\text{PDO}(n)$ in the sense that the coefficient of q^n in $C_k(q)$ provides the contribution to $\text{PDO}(n)$ where the partitions in question have exactly k different part sizes.

A Different View of the Generating Function

OK, back to $\text{PDO}(n)$!

We now highlight two very important connections.

First, note that for a given k , $C_k(q)$ provides a natural refinement of the generating function of $\text{PDO}(n)$ in the sense that the coefficient of q^n in $C_k(q)$ provides the contribution to $\text{PDO}(n)$ where the partitions in question have exactly k different part sizes.

Said from a generating function perspective,

$$\sum_{n \geq 0} \text{PDO}(n)q^n = \sum_{k \geq 0} C_k(q).$$

A Different View of the Generating Function

Secondly, we note that, in their 2013 *J. Reine Angew. Math.* paper, Andrews and Rose introduced the function

$$G(x, q) := 1 + 2 \sum_{n \geq 1} T_{2n}(x/2)q^{n^2}$$

where, for $n \geq 0$, $T_n(x)$ is the n^{th} Chebyshev polynomial (of the first kind) defined by $T_n(\cos \theta) = \cos(n\theta)$.

Then we have the following:

Theorem: For every $n \geq 0$, we have

$$\sum_{\lambda \in \mathcal{PDO}(2n)} x^{\ell_d(\lambda)} = \sum_{k=0}^n \left(\sum_{\alpha \in \mathcal{PDO}(k)} x^{\ell_d(\alpha)} \right) \left(\sum_{\beta \in \mathcal{PDO}(n-k)} x^{\ell_d(\beta)} \right).$$

Equivalently, writing

$$\text{PDO}(x, q) := \sum_{\lambda \in \mathcal{PDO}} x^{\ell_d(\lambda)} q^{|\lambda|},$$

we have for all $n \geq 0$,

$$[q^{2n}] \text{PDO}(x, q) = [q^n] (\text{PDO}(x, q))^2.$$

Background

A Different View
of the Generating
Function

Our Refinements

Closing Thoughts

Our Refinements

After incorporating the 2-dissections for $G(x, q)$ and the generating function for $\bar{p}(n)$, along with performing some simplifications, we see that we need to prove the following:

$$\frac{f_4^5}{f_2^2 f_8^2} \left(1 + 2 \sum_{n \geq 1} T_{4n} q^{2n^2} \right) + 4q \frac{f_8^2}{f_4} \left(\sum_{n \geq 1} T_{4n-2} q^{2n^2-2n} \right) = \left(1 + 2 \sum_{n \geq 1} T_{2n} q^{n^2} \right)^2,$$

where we have suppressed the argument $x/2$ in all Chebyshev polynomials $T_n(x/2)$.

Our Refinements

As an interesting aside, note that

$$\frac{f_4^5}{f_2^2 f_8^2} \quad \text{and} \quad \frac{f_8^2}{f_4}$$

are clearly related to Ramanujan's theta functions

$$\varphi(q) := 1 + 2 \sum_{n \geq 1} q^{n^2} = \frac{f_2^5}{f_1^2 f_4^2},$$

$$\psi(q) := \sum_{n \geq 1} q^{\binom{n}{2}} = \frac{f_2^2}{f_1}.$$

Our Refinements

As an interesting aside, note that

$$\frac{f_4^5}{f_2^2 f_8^2} \quad \text{and} \quad \frac{f_8^2}{f_4}$$

are clearly related to Ramanujan's theta functions

$$\varphi(q) := 1 + 2 \sum_{n \geq 1} q^{n^2} = \frac{f_2^5}{f_1^2 f_4^2},$$

$$\psi(q) := \sum_{n \geq 1} q^{\binom{n}{2}} = \frac{f_2^2}{f_1}.$$

After a bit more simplification, we reduce the above equation to an even simpler equality, and we close out the proof then via a pair of elementary bijections.

Our Refinements

In the time that remains, let me provide a two-parameter refinement of the original curious identity (which is a one-parameter refinement of our first refinement).

As an example, $l_r(3' + 3 + 1 + 1 + 1', 5' + 5 + 3') = 1$ since only the part 3 is found in both α and β .

Now let

$$P_2(x, y, q) := \sum_{(\alpha|\beta) \in \mathcal{PDO} \times \mathcal{PDO}} x^{\ell_d(\alpha) + \ell_d(\beta)} y^{2l_r(\alpha, \beta)} q^{|\alpha| + |\beta|}.$$

We then have the following:

Our Refinements

$$\begin{aligned}P_1(x, y, q) &= \prod_{m \geq 1} \left(1 + 2x \frac{q^{4m-2}}{(1 - q^{4m-2})^2} + xy \frac{q^{2m-1}(1 + q^{4m-2})}{(1 - q^{4m-2})^2} \right) \\ &= \prod_{m \geq 1} \left(1 + xy \frac{q^{2m-1}}{(1 - q^{2m-1})^2} + 2x(1 - y) \frac{q^{4m-2}}{(1 - q^{4m-2})^2} \right),\end{aligned}$$

and

$$\begin{aligned}P_2(x, y, q) &= \prod_{m \geq 1} \left(1 + 2x \frac{q^{2m-1}}{(1 - q^{2m-1})^2} + x^2 y^2 \left(\frac{q^{2m-1}}{(1 - q^{2m-1})^2} \right)^2 \right) \\ &= \prod_{m \geq 1} \left(\left(1 + xy \frac{q^{2m-1}}{(1 - q^{2m-1})^2} \right)^2 + 2x(1 - y) \frac{q^{2m-1}}{(1 - q^{2m-1})^2} \right).\end{aligned}$$

Our Refinements

Moreover, for all $n \geq 0$ we have

$$[q^{2n}]P_1(x, y, q) = [q^n]P_2(x, y, q).$$

Closing Thoughts

Closing Thoughts

I'll close with a few comments:

- ▶ As a complete sidenote, if we return to the function $PD(n)$ of Andrews, Lewis, and Lovejoy, where there are no parity restrictions on the parts in question, then we see that

$$\sum_{n \geq 0} PD(n)q^n = \sum_{k \geq 0} A_k(q).$$

Closing Thoughts

I'll close with a few comments:

- ▶ As a complete sidenote, if we return to the function $PD(n)$ of Andrews, Lewis, and Lovejoy, where there are no parity restrictions on the parts in question, then we see that

$$\sum_{n \geq 0} PD(n)q^n = \sum_{k \geq 0} A_k(q).$$

It is not clear whether this can be utilized in any beneficial way; even so, it's worth highlighting as this yields (in analogous fashion) a refinement of the function $PD(n)$ by the number of parts present in each such partition.

Closing Thoughts

I'll close with a few comments:

- ▶ In essence, our proofs reduce to proving a few trigonometric identities (which are, at their core, statements about Chebyshev polynomials). For the most part, once we have reduced the work to these identities, their proofs are relatively straightforward.
